

Cloud Deployment Architecture

A guide to navigating
Public, Private, Hybrid,
and Community models.

Who owns the hardware, and who uses it?

Provider Owned

The cloud is simply the relocation of computing resources.

Organization Owned

Deployment models are defined by two variables: who maintains the underlying hardware, and who is granted access to the configured resources.

What to build when you have zero existing infrastructure

The Baseline: By far the most common cloud model.

The Mechanics: Resources of the third-party provider are publicly shared.

The Access: None of the resources are physically present within your organization. Everything is accessed over the public internet.

Shared underlying hardware does not mean shared data

Leveraging robust existing infrastructure internally

The Baseline: The exact opposite of the public cloud. Resources are only privately shared.

The Mechanics: Implemented and maintained entirely internally by the organization.

The Access: No clients from the public internet. Access is strictly determined by the organization, routed over internal networks or secured internet channels.

Extending central data center resources to remote locations

What happens when your internal infrastructure runs out of space?

The Hybrid Cloud: A combination of both public and private cloud models.

The Catalyst: Organizations typically adopt this configuration when they are expanding rapidly and need to supplement their existing resources.

Supplementing capacity without purchasing new local hardware

Designing a shared architecture for joint business ventures

The Baseline: The least common deployment model.

The Mechanics: Shared infrastructure restricted to a controlled group of businesses with similar needs.

The Ideal Use: Perfect for joint projects where multiple external entities must collaborate deeply.

Carving out a private collaboration space inside a public provider

Shared Costs:

Orgs pool their resources to share the cost of a single public cloud subscription.

Shared Access:

All participating organizations can communicate, participate, and access necessary project resources.

The Paradox:

It operates as a private, exclusive cloud space, but relies entirely on a public cloud provider's infrastructure.

The Cloud Model Diagnostic Matrix

	Public	Private	Hybrid	Community
Infrastructure Ownership	Third-Party Provider	Internal Organization	Combined Internal/External	Third-Party Provider
Tenancy	Multi-Tenant (Public)	Single-Tenant (Internal Only)	Mixed	Shared Group (Multi-Org)
Access Method	Public Internet	Private Network/Internet	Combined	Public Internet
Ideal Scenario	Zero existing infrastructure	Robust existing infrastructure	Supplementing tapped-out capacity	Joint business projects

The Deployment Decision Engine

There is a model to suit any organizational need

Public

Private

Hybrid

Community

“Whether you are starting with zero infrastructure or extending a robust corporate data center, cloud services provide an architectural fit for any specific circumstance.”
